All electromagnetic waves consist of electric and magnetic fields propagating in the same direction of travel, but perpendicular to each other. Along the length of a normal transmission line, both electric and magnetic fields are perpendicular (transverse) to the direction of wave travel.

The line-of-sight propagation will not be smooth if there occurs any obstacle in its transmission path. As the signal can travel only to lesser distances in this mode, this transmission is used for infrared or microwave transmissions. Ground Wave Propagation. Ground wave propagation of the wave follows the contour of earth.

Transmission lines may also be dispersive, which means the propagation velocity on the line is not constant with frequency For example the frequency components of square wave (re- call odd harmonics only) each propagate at a different velocity, meaning the waveform becomes smeared Dispersion is very important to high speed digital transmission (fiber optic and wired networks alike) The longer the line, the greater the impact

Propagation Constant of a Transmission line. The propagation constant for any conducting lines (like copper lines) can be calculated by relating the primary line parameters. $\gamma = \sqrt{(Z'Y')}$ Where, $Z' = R + j\omega L$ Series impedance of line per unit length. $Y' = G + j\omega C$ The shunt admittance of line per unit length.

Any disturbance on a Travelling Waves on Transmission Lines or system such as sudden opening or closing of line, a short circuit or a fault results in the development of overvoltages or overcurrents at that point. This disturbance propagates as a travelling wave to the ends of the line or to a termination, such as, a sub-station.

Wave propagation—voltage and current—in transmission lines is usually handled by employing phasor analysis. In this context, it is crucial to understand that, in general, there are two waves traveling in opposite directions and that their relative phase changes along the line. Consequently, a standing wave is produced for voltage and current.

For a transmission line, the Heaviside condition of the telegrapher's equation tells us that the wavenumber must be proportional to frequency for the transmission of the wave to be undistorted in the time domain. This includes, but is not limited to, the ideal case of a lossless line.

Propagation constant - Wikipedia

A transmission line is drawn as two black wires. At a distance x into the line, there is current $I(x)$ travelling through each wire, and there is a voltage difference $V(x)$ between the wires. If the current and voltage come from a single wave (with no reflection), then $V(x) / I(x) = Z_0$, where Z_0 is the characteristic impedance of the line.
